# Dynamic Programming

Not a style of computer programming – a method for solving optimization problems developed in the 1950's:

*My first task was to find a name for multistage decision processes [...] I felt I had to do something to shield [...] the Air Force from the fact that I was really doing mathematics [...] Thus, I thought dynamic programming was a good name. It was something not even a Congressman could object to.*

(Richard Bellman, Autobiography, 1984)

Cut a steel rod of length  $n$  into integer-sized pieces to maximize total revenue:

|             |   |   |     |   |    |    |    |    |    |     |
|-------------|---|---|-----|---|----|----|----|----|----|-----|
|             | 1 | 2 | ... |   |    |    |    |    |    | $n$ |
| Length $i$  | 1 | 2 | 3   | 4 | 5  | 6  | 7  | 8  | 9  | 10  |
| Price $p_i$ | 1 | 5 | 8   | 9 | 10 | 17 | 17 | 20 | 24 | 30  |

## Problem Formalization

Solution space: *Partitions of  $n$* : numbers  $i_1, i_2, \dots, i_k$ , so that  $n = i_1 + i_2 + \dots + i_k$

Value function: Partition  $i_1, i_2, \dots, i_k$  has value  $p_{i_1} + p_{i_2} + \dots + p_{i_k}$ .

Objective: Find optimal value and optimal partition:

$$r_n = \max(p_{i_1} + p_{i_2} + \dots + p_{i_k})$$

$$s_n = \arg \max(p_{i_1} + p_{i_2} + \dots + p_{i_k})$$

where the maximum is taken over all possible solutions  $i_1, i_2, \dots, i_k$ .

General optimization scenario:

General optimization scenario:

General optimization scenario:

- ▶ Instead of *maximizing* a *value* function, one may *minimize* a *cost* function
- ▶ Another example: Maximal subarray problem
  - ▶ Solution space: set of all subarrays of input array
  - ▶ Value function: sum of values in subarray

Brute-force approach for solving rod-cutting problem with  $n = 4$ : compute values of all possible solutions:

| Solution | Value           |
|----------|-----------------|
| 1,1,1,1  | $4 = 1+1+1+1$   |
| 1,1,2    | $7 = 1 + 1 + 5$ |
| 1,3      | $9 = 1 + 8$     |
| 2,2      | $10 = 5 + 5$    |
| 4        | 9               |

→ best value: 10, best solution: 2,2.

👉 the number of candidate solutions is exponential in  $n$

👉 brute force approach can only work for very small values of  $n$

## Optimal Substructure

Consider optimal solution  $i_1, i_2, \dots, i_k$  for problem size  $n$ :

Then:  $i_2, \dots, i_k$  is optimal solution for problem size  $n - i_1$ , and the optimal value for size  $n$  is  $p_{i_1} + r_{n-i_1}$

$$r_n = \max_{1 \leq i \leq n} (p_i + r_{n-i})$$

 The optimal solution for a given problem instance incorporates optimal solution(s) of simpler/smaller subproblems.

**input** : Positive integer  $n$ , Array  $p[1 .. n]$  of positive integers

**output**: Value of optimal rod-cutting solution for problem size  $n$  and price table  $p$

CUTROD( $p, n$ )

```
1 if  $n==0$  then  
2   return 0  
3  $q = -\infty$   
4 for  $i=1$  to  $n$  do  
5    $q = \max(q, p[i] + \text{CutRod}(p, n - i))$   
6 return  $q$ 
```

**input** : Positive integer  $n$ , Array  $p[1 \dots n]$  of positive integers

**output**: Value of optimal rod-cutting solution for problem size  $n$  and price table  $p$

CUTROD( $p, n$ )

```

1 if  $n==0$  then
2   return 0
3  $q = -\infty$ 
4 for  $i=1$  to  $n$  do
5    $q = \max(q, p[i] + \text{CutRod}(p, n - i))$ 
6 return  $q$ 

```

Concrete recursion tree for CUTROD( $p, 4$ ):

Number of nodes in tree for CUTROD( $p, n$ ):

$$T(n) = 1 + \sum_{j=0}^{n-1} T(j)$$

Solution:

$$T(n) = 2^n$$

How fast (worst-case) can we solve the rod cutting problem using dynamic programming?

A  $2^n$

B  $n^3$

C  $n^2$

D  $n \lg n$

E  $n$

Computations performed in subtrees with the same root are identical!

**Idea:** Instead of repeating identical computations, store the results and look them up!

Computations performed in sub-trees with the same root are identical!

**Idea:** Instead of repeating identical computations, store the results and look them up!

## Top-down Computation with Memoization

MEMOIZEDCUTROD( $p, n$ )

- 1 let  $r[1 \dots n]$  be a new array
- 2 **for**  $i=0$  to  $n$  **do**
- 3      $r[i] = -\infty$
- 4 **return** MEMOIZEDCUTRODAUX( $p, n, r$ )

MEMOIZEDCUTRODAUX( $p, n, r$ )

- 1 **if**  $r[n] \geq 0$  **then**
- 2     **return**  $r[n]$
- 3 **if**  $n == 0$  **then**
- 4      $q = 0$
- 5 **else**
- 6      $q = -\infty$
- 7     **for**  $i=1$  to  $n$  **do**
- 8          $q = \max(q,$   
             $p[i] + \text{MemoizedCutRodAux}(p, n-i, r))$
- 9      $r[n] = q$
- 10 **return**  $q$

## Bottom-Up Version

BOTTOMUPCUTROD( $p, n$ )

```
1 let  $r[0..n]$  be a new array
2  $r[0] = 0$ 
3 for  $j=1$  to  $n$  do
4      $q = -\infty$ 
5     for  $i=1$  to  $j$  do
6          $q = \max(q, p[i] + r[j - i])$ 
7      $r[j] = q$ 
8 return  $r[n]$ 
```

Complexity:  $\Theta(n^2)$

Recursion tree for memoized cut rod:

Subproblem Graph

The **Subproblem Graph** for  $\text{SOMEALGORITHM}(x)$

- contains one node for each distinct recursive function call occurring in the concrete recursion tree of  $\text{SOMEALGORITHM}(x)$
- an edge between node  $z$  and node  $y$  if evaluating  $\text{SOMEALGORITHM}(z)$  leads to a call  $\text{SOMEALGORITHM}(y)$

 the edges in the subproblem graph correspond to the edges in the recursion tree with memoization

 the complexity of top-down computation with memoization is  $\Omega(e)$ , where  $e$  is the number of edges in the subproblem graph.

MEMOIZEDCUTROD and BOTTOMUPCUTROD only compute the *value* of the optimal solution, not the solution itself!

```

    EXTENDEDOTTOMUPCUTROD( $p, n$ )
1  let  $r[1 \dots n]$  and  $s[1 \dots n]$  be new arrays
2   $r[0] = 0$ 
3  for  $j=1$  to  $n$  do
4       $q = -\infty$ 
5      for  $i=1$  to  $j$  do
6          if  $q < p[i] + r[j-i]$  then
7               $q = p[i] + r[j-i]$ 
8               $s[j] = i$ 
9       $r[j] = q$ 
10 return  $r[n]$ 

```

Result for  $n = 10$ :

| $i$    | 0 | 1 | 2 | 3 | 4  | 5  | 6  | 7  | 8  | 9  | 10 |
|--------|---|---|---|---|----|----|----|----|----|----|----|
| $r[i]$ | 0 | 1 | 5 | 8 | 10 | 13 | 17 | 18 | 22 | 25 | 30 |
| $s[i]$ | 0 | 1 | 2 | 3 | 2  | 2  | 6  | 1  | 2  | 3  | 10 |

## Optimal Binary Search Tree

**Before** (Red-Black Trees etc.): goal is to construct BST with  $\lg n$  *worst-case* complexity for all operations *insert, delete, search*.

**Now**: goal is to construct BST with best *average-case* complexity for repeated *search* operations.

### Example

- ▶ Want to build search tree for keys  $k_1 < k_2 < k_3 < k_4 < k_5$
- ▶ Have the following probabilities:
  - ▶  $p_i$ : probability that search is for key  $k_i$  ( $i = 1, \dots, 5$ )
  - ▶  $q_i$ : probability that search is for key in between  $k_i$  and  $k_{i+1}$  ( $i = 1, \dots, 4$ ), a key less than  $k_1$  ( $i = 0$ ), or greater than  $k_5$  ( $i = 5$ )

| $i$   | 0    | 1    | 2    | 3    | 4    | 5   |
|-------|------|------|------|------|------|-----|
| $p_i$ |      | 0.15 | 0.1  | 0.05 | 0.1  | 0.2 |
| $q_i$ | 0.05 | 0.1  | 0.05 | 0.05 | 0.05 | 0.1 |

$$\sum_{i=1}^5 p_i + \sum_{i=0}^5 q_i = 1$$

 Want to minimize average search time for repeated searching according to these probabilities

Two candidate trees. Unsuccessful searches represented by leaves with dummy keys  $d_0, \dots, d_5$ :

(a)

(b)

Computing average search time (search cost for (dummy) key:  $1 + \text{depth of node}$ ):

| Node  | Probability | Depth | (a)<br>Contribution | Depth | (b)<br>Contribution |
|-------|-------------|-------|---------------------|-------|---------------------|
| $k_1$ | 0.15        | 1     | 0.3                 | 1     | 0.3                 |
| $k_2$ | 0.1         | 0     | 0.1                 | 0     | 0.1                 |
| $k_3$ | 0.05        | 2     | 0.15                | 3     | 0.2                 |
| $k_4$ | 0.1         | 1     | 0.2                 | 2     | 0.3                 |
| $k_5$ | 0.2         | 2     | 0.6                 | 1     | 0.4                 |
| $d_0$ | 0.05        | 2     | 0.15                | 2     | 0.15                |
| $d_1$ | 0.1         | 2     | 0.3                 | 2     | 0.3                 |
| $d_2$ | 0.05        | 3     | 0.2                 | 4     | 0.25                |
| $d_3$ | 0.05        | 3     | 0.2                 | 4     | 0.25                |
| $d_4$ | 0.05        | 3     | 0.2                 | 3     | 0.2                 |
| $d_5$ | 0.1         | 3     | 0.4                 | 2     | 0.3                 |
| Total |             |       | 2.8                 |       | 2.75                |

BST for (dummy) keys  $d_0, k_1, \dots, d_{r-1}, k_r, \dots, k_n, d_n$  with  $k_r$  the root:

 every subtree of a BST contains a contiguous range of (dummy) keys  $d_{i-1}, k_i, d_i, \dots, k_j, d_j$ .

### Defining $e[i, j]$

- For tree  $T$  containing  $d_{i-1}, k_i, d_i, \dots, k_j, d_j$ , the expected search cost is

$$e_T = \sum_{h=i}^j p_i \cdot (\text{depth}_T(k_i) + 1) + \sum_{h=i-1}^j q_i \cdot (\text{depth}_T(d_i) + 1)$$

- $e[i, j]$ : minimum value of  $e_T$  for all possible trees  $T$  containing  $d_{i-1}, k_i, d_i, \dots, k_j, d_j$ .

**Recursion for  $e[i, j]$** 

Assuming the optimal tree for  $d_{i-1}, k_i, d_i, \dots, k_j, d_j$  has root  $k_r$  ( $i \leq r \leq j$ ). Then:

$$e[i, j] = e[i, r - 1] + e[r + 1, j] + w(i, j)$$

where

$$w(i, j) = \sum_{h=i}^j p_h + \sum_{h=i-1}^j q_h$$

Optimizing over possible choices of root:

$$e[i, j] = \begin{cases} q_{i-1} & \text{if } j = i - 1 \\ \min_{i \leq r \leq j} e[i, r - 1] + e[r + 1, j] + w(i, j) & \text{if } i \leq j \end{cases}$$

Subproblem graph for the computation of  $e[1, 4]$ :

Number of edges:  $\Theta(n^3)$

**Reminder :** 
$$e[i, j] = \begin{cases} q_{i-1} & \text{if } j = i - 1 \\ \min_{i \leq r \leq j} e[i, r - 1] + e[r + 1, j] + w(i, j) & \text{if } i \leq j \end{cases}$$

Grey area: not needed

Arrows indicate sequence in which array entries are computed

- ▶ Iteratively fill in matrix  $e[1 \dots n + 1, 0 \dots n]$ , so that when  $e[i, j]$  is computed all required  $e[i, r - 1]$  and  $e[r + 1, j]$  are already computed.
- ▶ In parallel, compute additional matrices:
  - ▶  $w[1 \dots n + 1, 0 \dots n]$  for the  $w(i, j)$  values
  - ▶  $root[1 \dots n, 1 \dots n]$  for the index of the optimal root
- ▶ Complexity:  $\Theta(n^3)$ .

The grid represents a 2D array  $e[i, j]$  with the following values:

| $j \backslash i$ | 1    | 2    | 3    | 4    | 5    | 6    |
|------------------|------|------|------|------|------|------|
| 5                | 2.75 | 2.00 | 1.30 | 0.90 | 0.50 | 0.10 |
| 4                | 1.75 | 1.20 | 0.60 | 0.30 | 0.05 | Gray |
| 3                | 1.25 | 0.70 | 0.25 | 0.05 | Gray | Gray |
| 2                | 0.90 | 0.40 | 0.05 | Gray | Gray | Gray |
| 1                | 0.45 | 0.10 | Gray | Gray | Gray | Gray |
| 0                | 0.05 | Gray | Gray | Gray | Gray | Gray |

|     |   |           |      |      |      |      |      |
|-----|---|-----------|------|------|------|------|------|
|     |   | $e[i, j]$ |      |      |      |      |      |
|     | 5 | 2.75      | 2.00 | 1.30 | 0.90 | 0.50 | 0.10 |
|     | 4 | 1.75      | 1.20 | 0.60 | 0.30 | 0.05 |      |
|     | 3 | 1.25      | 0.70 | 0.25 | 0.05 |      |      |
| $j$ | 2 | 0.90      | 0.40 | 0.05 |      |      |      |
|     | 1 | 0.45      | 0.10 |      |      |      |      |
|     | 0 | 0.05      |      |      |      |      |      |
|     |   | 1         | 2    | 3    | 4    | 5    | 6    |
|     |   | $i$       |      |      |      |      |      |

|     | $root[i, j]$ |   |   |   |   |   |
|-----|--------------|---|---|---|---|---|
| $j$ | 1            | 2 | 3 | 4 | 5 | 6 |
| 5   | 2            | 4 | 5 | 5 | 5 |   |

# Summary

## Optimization Problems

The computational problem can be defined as optimization of a value function over a solution space.

## Optimal Substructure

The optimal solution contains optimal solutions of (smaller) subproblems.

Often: optimal solution is determined by:

- ▶ one initial (optimal) choice
  - ▶ Rod cutting: choice of first length to cut off
  - ▶ Optimal BST: choice of key at the root
- ▶ optimal solutions of smaller subproblems
  - ▶ Rod cutting: optimal cutting of remaining length of rod
  - ▶ Optimal BST: optimal BST for keys left and right of root

## Overlapping Subproblems

In *recursive solution* approach identical subproblems occur at several nodes of the concrete recursion tree.

- ▶ Rod cutting: optimal cutting of rod of length  $i$
- ▶ Optimal BST: optimal BST for keys in range  $k_i, \dots, k_j$

Typical: subproblems are defined by 1,2,3, ... (a small number) integer arguments.

**Subproblem graph:** graph obtained from concrete recursion tree by merging nodes representing identical subproblems.

## Top-Down Solution

Use recursive computation, save results of subproblems already solved (Memoization, Caching)

## Bottom-Up Computation

Typical scenario: subproblems are defined by  $k$  integer arguments (e.g.  $k = 2$ ). Then: iteratively fill up a  $k$ -dimensional array containing the solutions for all subproblems needed to solve the original problem.

## Complexity

A lower bound is given by the number of edges in the subproblem graph:

- ▶ In top-down approach, an edge represents a recursive function call
- ▶ In bottom-up approach, an edge represents an access to an already computed subproblem solution

Typical: this lower bound is also an upper bound

## Time-Space Tradeoff

Dynamic programming ...

- ▶ saves time compared to recursive solutions
- ▶ needs extra space to store solutions of subproblems
